### Abstract

---

Four decisions, each locally reasonable, each under-evidenced, produced a decade without networking in the C++ standard.

This paper assembles the findings of five companion papers into a single causal chain: the unification of executors (2014, [P4094R0](#)<sup>[1]</sup>), the basis-operation pivot (2019, [P4095R0](#)<sup>[2]</sup>), the P2464 diagnosis (2021, [P4096R0](#)<sup>[3]</sup>), the networking claim in the poll (2021, [P4097R0](#)<sup>[4]</sup>), and the evidence base for the trajectory

(P4098R0<sup>[5]</sup>). Each paper documents one decision point. This paper places them in sequence, documents what is now available that was not available when those decisions were made, and credits the work that produced the tools the committee now has.

## 1. Disclosure

---

This paper is part of the Network Endeavor (P4100R0), a thirteen-paper project to bring networking to C++29 using a coroutine-native approach. The author developed and maintains Corosio<sup>[6]</sup> and Capy<sup>[7]</sup> and believes coroutine-native I/O is the correct foundation for networking in C++. Coroutine-native I/O does not provide the sender composition algebra - `retry`, `when_all`, `upon_error` - that `std::execution` provides. The author provides information, asks nothing, and serves at the pleasure of the chair.

The committee has been trying to standardize networking since 2005. This retrospective examines the published record to identify the failure modes that prevented delivery, so the next attempt can avoid them. Its findings stand on their own. That effort requires re-examining consequential papers, including papers written by people the author respects.

---

## 2. The Causal Chain

---

| Year | Decision                                           | Rationale                                                             | Published evidence                                                                                                | Companion paper        |
|------|----------------------------------------------------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|------------------------|
| 2014 | Three independent executor models unified into one | Shared execution contexts; N x M explosion; synchronization coherence | One hypothetical code snippet. No prototype. No survey. No deployment data showing friction from separate models. | P4094R0 <sup>[1]</sup> |

---

| Year      | Decision                                                                                   | Rationale                                                                | Published evidence                                                                                                                                 | Companion paper                        |
|-----------|--------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| 2019      | <code>execute(F&amp;&amp;)</code> diagnosed as deficient; Cologne pivot to Sender/Receiver | No error channel, no cancellation signal, no zero-allocation scheduling  | Diagnosis under the work framing only. Continuation framing not examined. Networking use case not analyzed.                                        | <a href="#">P4095R0</a> <sup>[2]</sup> |
| 2021      | P2464R0 diagnosis applied to Networking TS; networking set aside                           | Executor is a “work-submitter”; no error channel; no generic composition | Analysis under the work framing only. Continuation framing not examined.                                                                           | <a href="#">P4096R0</a> <sup>[3]</sup> |
| 2021      | Poll: sender/receiver “a good basis... including networking” - consensus in favor          | P2300 deployments at Facebook, NVIDIA, Bloomberg                         | Deployments are for GPU dispatch, thread pools, and infrastructure. No sender-based networking deployment. No prototype. One hypothetical example. | <a href="#">P4097R0</a> <sup>[4]</sup> |
| 2014-2026 | Twenty claims shaped the trajectory; evidence documented where it exists                   | Various                                                                  | Evidence concentrated in GPU/infrastructure domains. Networking evidence column empty for most claims.                                             | <a href="#">P4098R0</a> <sup>[5]</sup> |

Each decision was locally reasonable. Each was made by experienced practitioners under real constraints. No decision was careless. The record is now complete.

### 3. What the Committee Got Right

[P2300R10](#)<sup>[8]</sup>, “std::execution,” is a genuine achievement. The sender/receiver model provides structured concurrency, sender composition, completion signatures as type-level contracts, and a customization point model that enables heterogeneous dispatch. [P2470R0](#)<sup>[9]</sup> documented deployments at Facebook (“monthly users number in the billions”), NVIDIA (“fully invested in P2300... we plan to ship in production”), and Bloomberg (experimentation). GPU dispatch, infrastructure, HPC - the domains where compile-time work graphs, zero-allocation pipelines, and heterogeneous composition deliver their full value.

The people who built this - Eric Niebler, Kirk Shoop, Lewis Baker, Lee Howes, Michał Dominiak, and their collaborators - identified genuine structural problems in the executor concept and proposed a design that solved them. P1525R0<sup>[10]</sup> documented real deficiencies in `execute(F&&)` under the work framing. The sender/receiver model addressed all four. The committee adopted it. It shipped.

The unification effort that preceded P2300 - P0443<sup>[11]</sup>, more than 100 papers, organizations spanning Google, NVIDIA, Sandia, Codeplay, Facebook, Microsoft, and RedHat - was a sustained, genuine effort to find common ground. The breadth of participation was extraordinary. The compromise was real.

These are facts. This series documents them alongside the facts about what was not examined. Both belong in the record.

---

## 4. What Is Now Available

---

The following capabilities exist in 2026 that did not exist when the decisions in Section 2 were made.

C++20 coroutines were ratified in 2020. They did not exist in 2014 when the unification decision was made, or in 2019 when P1525R0<sup>[10]</sup> diagnosed the basis operation. The coroutine executor concept constrains the handle type to `coroutine_handle<>`, restoring the type constraint that the rename from `dispatch / post / defer` to `execute(F&&)` removed.

The coroutine executor concept was published in P4003R0<sup>[12]</sup> (2026). It provides `dispatch(coroutine_handle<>)` and `post(coroutine_handle<>)` - continuation-scheduling primitives with a typed handle. The four deficiencies P1525R0<sup>[10]</sup> identified do not arise under this concept (P4095R0<sup>[2]</sup> Section 4).

The two-framing distinction - work framing vs. continuation framing - was documented in P4094R0<sup>[1]</sup> Section 6. The continuation framing was the original framing (P0113R0<sup>[13]</sup>, 2015). The work framing replaced it through two stages of simplification. No published paper in the causal chain discussed the shift. The distinction is now available for the committee to apply.

The rationale-loss mechanism was documented in P4094R0<sup>[1]</sup> Section 6.3. API surfaces transfer between papers; design rationale does not, unless someone actively carries it forward. The continuation framing was carried by institutional knowledge rather than by the type system. When the property hint was removed by authors who did not carry that knowledge forward, the framing dropped out. This is a structural property of multi-author standardization, not a criticism of any individual.

Interop bridges between the coroutine model and the sender model were published in P4092R0<sup>[14]</sup> and P4093R0<sup>[15]</sup>. The two models can coexist and interoperate.

`std::execution::task` (P3552R3<sup>[16]</sup>) is simultaneously a coroutine and a sender. The committee has already voted to ship a type that fuses two async models into one. The price of two models has been paid.

---

## 5. The Design Fork

---

### Awaitable

```
struct read_awaitable
{
    bool await_ready();
    void await_suspend(
        std::coroutine_handle<> h);
    // caller erased
    io_result<size_t>
    await_resume();
};
```

### Sender

```
template<class Receiver>
struct read_operation
{
    Receiver rcvr_;
    // caller stamped in
    void start() noexcept;
};
```

`coroutine_handle<>` erases the caller. `connect(sender, receiver)` stamps the caller into the operation state. The first choice produces type-erased streams, separate compilation, and ABI stability - properties that have been difficult to achieve in twenty years of networking attempts. The second produces full pipeline visibility, zero-allocation composition, and compile-time work graphs - the properties that make `std::execution` valuable for GPU dispatch, heterogeneous execution, and infrastructure. Neither model can acquire the other's properties without surrendering its own. The technical analysis is in P4088R0<sup>[17]</sup>.

The committee has already voted to ship `std::execution::task` (P3552R3<sup>[16]</sup>), a type that is simultaneously a coroutine and a sender. The price of two async models has been paid. The question is whether both models should carry I/O facilities that exploit their respective strengths.

---

## 6. Anticipated Objections

---

Q: This is hindsight bias.

A: The companion papers document what evidence was available at the time each decision was made. The questions in Sections 4 and 5 of P4094R0<sup>[1]</sup> could have been asked in 2014. They were not. The two-framing analysis in P4095R0<sup>[2]</sup> could not have been performed in 2019 because C++20 coroutines did not yet exist. This paper distinguishes between the two cases.

Q: P2300 will eventually cover networking.

A: It might. The record documents what has shipped as of 2026. No sender-based networking deployment has been published. The committee now has two models to evaluate. Time will tell which serves networking better, or whether both do.

Q: Two models fragment the ecosystem.

A: The committee has shipped multiple design approaches for the same domain before: `iostream` and `std::format / std::print`; C++17 execution policies and P2300 senders with `bulk . std::execution::task` (P3552R3<sup>[16]</sup>) is simultaneously a coroutine and a sender. The committee has already chosen coexistence.

Q: You are arguing for your own library.

A: Section 1 discloses this. The causal chain in Section 2 is assembled from the published record. The evidence stands or falls on the sources, not on who assembled them.

---

## Acknowledgments

---

The author thanks Chris Kohlhoff for the executor model that started the journey, for twenty years of Boost.Asio deployment, for the candid retrospective in P1791R0<sup>[18]</sup>, and for N3747<sup>[19]</sup>'s universal async model; Eric Niebler, Kirk Shoop, Lewis Baker, and Lee Howes for the sender/receiver model, for P1525R0<sup>[10]</sup>'s genuine structural insights, and for P2300<sup>[8]</sup>; Michał Dominiak for the editorial work that brought P2300R10<sup>[8]</sup> to adoption; Jared Hoberock, Michael Garland, and Chris Mysisen for P0443<sup>[11]</sup>, P0761R2<sup>[20]</sup>, and years of compromise in pursuit of a unified model; Ville Voutilainen for P2464R0<sup>[21]</sup>'s analytical framework, which provided the evaluation criteria this series applies; Bryce Adelstein Lelbach for the published poll outcomes in P2453R0<sup>[22]</sup> and P2400R2<sup>[23]</sup> that made this analysis possible; Dietmar Kühl for P2762R2<sup>[24]</sup> and `beman::execution`; Detlef Vollmann for P1256R0<sup>[25]</sup>; Jonathan Müller for P3801R0<sup>[26]</sup>; Peter Dimov for technical corrections on earlier drafts; Steve Gerbino and Mungo Gill for `Capy`<sup>[7]</sup> and `Corosio`<sup>[6]</sup> implementation work; Klemens Morgenstern for Boost.Cobalt and the cross-library bridge examples; Jamie Allsop and Richard Hodges for co-authoring P2469R0<sup>[27]</sup>; and the national body members who raised concerns at St. Louis.

The effort to bring async programming to C++ has been genuine, sustained, and conducted by people the author respects. This series documents the record. The committee will decide what to do with it.
